## DECLARATION

I hereby attest that I am the single author of this thesis and that no part of it, nor the entire thesis, has been submitted to any other university or institution for a degree.

I certify that the project report titled "Review paper on antidiabetic plant in Bangladesh" submitted to Daffodil International University's Department of Pharmacy is an original work completed by me under the supervision of Farjana Islam Aovi (Assistant professor, Department of pharmacy, Daffodil International University).

The facts and information included in the report are accurate to the best of my knowledge.

Sadia Afrin Shanchita  
ID: 213-46-380  
Batch: 13<sup>th</sup>  
Department of Pharmacy  
Daffodil International University

Supervisor  
Farzana Islam Aovi  
Assistant Professor  
Department of Pharmacy  
Daffodil International University

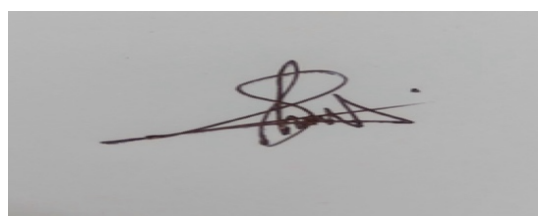

## ACKNOWLEDGEMENT

I owe a great debt of gratitude to my honorable project supervisor, **Farjana Islam Aovi** Assistant professor, Department of Pharmacy, Daffodil International University, for her brilliant leadership and steady oversight, as well as for providing vital information about the project and assisting me in completing it.

I'd like to extend my heartfelt greetings to **Dr. Muniruddin Ahmed**, Professor and Head, Daffodil International University's Department of Pharmacy.

I'd also want to express my appreciation to all of the teachers at Daffodil International University's Pharmacy Department, as well as other members, for their great collaboration with us.

Finally, I'd want to convey my thanks to my parents and other family members for their unwavering support and encouragement in completing this project.

Sadia Afrin Shanchita

## **DEDICATION**

*I dedicate this work to Almighty Allah first, and then to my family, my teachers and friends.*

## ABSTRACT

Diabetes mellitus, one of the most prevalent metabolic disorders, currently affects 2.8% of people worldwide, and by the year 2025, this percentage is projected to rise to 5.4%. Herbal cures have long been recognized as effective medical treatments, and they are now progressively playing a larger role in contemporary, high-tech medicine. The aim of this study was to determine whether or not Bangladesh uses anti-diabetic herbs. A literature review served as the analysis strategy in this investigation. The 15 papers being examined for this study were primarily written between the years of 1999 and 2022. Several websites, including Google Scholar and PubMed, were used to prepare the literature search for this investigation. The root (11%), the seed (11%), the complete plant (11%), the flower (3%), and the rhizome (1%), all components of the plant, the bark (9%), the stem (6%), the flower (3%), and the rhizome (1%). This review also explores how these plants' therapeutic properties can be used to treat diabetes mellitus. Clinical studies suggest that aloe vera gel may be a safe alternative to conventional antihyperglycemic and anti hypercholesterolemic medications for persons with type 2 diabetes. This is because it has little to no effect on other normal blood lipid levels or liver/kidney function. In a study, rabbits were fed aloe vera to investigate how it altered their fasting blood sugar levels. Aloe vera and glibenclamide both reduce blood sugar by 28% and 37%, respectively.

**Keywords:** Antidiabetic, Pharmacological, Hyperglycemia, Drug.

# Chapter One: Introduction

## 1.1.Diabetes

Hyperglycemia (high blood sugar levels) is a characteristic of the metabolic illness known as diabetes mellitus (or diabetes mellitus). Common symptoms include an increase in urine, thirst, and appetite. Uncontrolled Diabetes can lead to several serious consequences, some of which are fatal. Death, diabetic ketoacidosis, and hyperosmolar hyperglycemia are all possible acute outcomes of untreated Diabetes. Heart disease, stroke, chronic kidney disease, foot ulcers, nerve damage, eye damage, and cognitive impairment are only a few of the very serious long-term impacts [2]. [3] It's possible that the pancreas isn't making enough insulin or that the body's cells aren't utilizing the insulin produced as effectively as they should. A hormone called insulin helps glucose enter cells so that it may be used as fuel. Diabetes mellitus can have one of three forms: When beta cells in the pancreas start to go, the inability to produce enough insulin results in type 1 diabetes. Juvenile Diabetes or insulin-dependent diabetic Mellitus are no longer used terms to describe these conditions. When the immune system attacks the body, beta cells are killed. However, it is unknown what triggers this autoimmune reaction. Type 1 diabetes can occur in adults, but it typically strikes adolescents and teenagers. Insulin resistance, a condition where cells no longer respond to insulin as intended, is the underlying cause of type 2 diabetes. In the later stages of the disease, insulin insufficiency could appear. Previously, the medical term for this disorder was adult-onset Diabetes, also known as non-insulin-dependent diabetes mellitus. The majority of persons with type 2 diabetes are over 60, however younger people are now more frequently affected by the condition as a result of increased childhood obesity rates. Being overweight and being inactive are the most prevalent risk factors. The third of the major three is Diabetes, which often exclusively affects pregnant women who have never had the condition before. After giving birth, blood sugar levels in diabetic women frequently return to normal. Type 2 diabetes is more likely to strike women who have had gestational Diabetes in the future. Insulin injections are the only method of treatment for type 1 diabetes. Paying attention to dietary practices, physical activity levels, body mass index, and cigarette smoking are necessary for both preventing and managing type 2 diabetes. If you have type 2 diabetes, you may use oral antidiabetic drugs in place of or in addition to insulin to manage your disease. [4] People who have this condition should pay close attention to their feet and eyes, as well as take steps to control their blood pressure. When taking certain oral drugs like insulin, low blood sugar levels might be

dangerous (hypoglycemia). Obesity and type 2 diabetes patients may gain from bariatric surgery. [5-6] Many women who previously had type 2 diabetes no longer do so after giving baby. [7] 90% of the 463 million persons with Diabetes in 2019 had type 2 diabetes, which affects about 8.8% of the adult population worldwide. Men and women pay approximately identical rates. [8] The majority of individuals now anticipate future increases in interest rates. Your risk of dying young is at least doubled if you have Diabetes. Over 4.2 million individuals are anticipated to pass away this year due to Diabetes worldwide. why it is the sixth largest cause of mortality worldwide. [9-10] In 2017, it was predicted that diabetes-related medical costs will reach \$727 billion globally. Nearly \$327 billion was spent in the United States in 2017 as a result of Diabetes. [11] Diabetic patients typically pay 2.3% more for healthcare than the general population. [12]

## **1.2.History of Diabetes**

Diabetes was one of the first diseases to be recorded; it was described in Egyptian literature from around 1500 BCE as "too much emptying of the urine" [13]. The Ebers papyrus advises consuming a certain liquid to reduce these symptoms. Most likely, the first instance of the disease to be identified and reported was type 1 diabetes. The condition was referred to as "honey urine" (or "madhumeha") by practitioners of traditional Indian medicine. Around 230 BCE, the Greek physician Apollonius of Memphis coined the name "diabetes." The word is Greek in origin and means "to pass through." Galen, one of the most well-known Roman doctors, claimed that during the course of his whole career, he had only seen two cases of the ailment. Other potential factors include a sedentary lifestyle and outdated food, as well as the late discovery of clinical symptoms. This ailment was known as "Diarrhea of the Urine" by Galen (diarrhea urinosa). [14-15] The first known treatise, written by Aretaeus of Cappadocia, offers a comprehensive examination of Diabetes (2nd or early 3rd century C.E.). He blamed the humid, heavenly environment of the "Pneumatic School" for the disease's signs and progression. He speculated that Diabetes was related to other illnesses and talked about separating the signs of Diabetes from those of snakebite, another likely cause of acute dehydration. Before his book's initial Latin publication in Venice in 1552, he was mostly unknown in the West. [16] Around 400–500 CE, Indian doctors Sushruta and Charaka distinguished between two types of Diabetes, one associated with youth and the other with obesity. The most effective diabetes treatment to date is insulin, which was created and

perfected by Canadian scientists Frederick Banting and Charles Herbert Best in 1921 and 1922. NPH, a very long-acting form of insulin, was created in the 1940s.

### 1.3. Types of Diabetes

- Type 1 diabetes.
- Type 2 diabetes.
- Gestational Diabetes.
- Maturity onset diabetes of the young (MODY)
- Neonatal Diabetes.
- Wolfram Syndrome.
- Alström Syndrome.
- Latent Autoimmune Diabetes in Adults (LADA)

#### **Type 1 diabetes**

An autoimmune disorder known as type 1 diabetes, or T1D, occurs when the body's immune system unintentionally assaults its own insulin-producing cells (beta cells). For cells to utilize glucose as fuel, they need the hormone insulin. In the event that no therapy is given, this results in hyperglycemia. [17] The most typical signs of high blood sugar include increased urination, thirst, hunger, and weight loss, all of which may be uncomfortable or even hazardous. [18] It may show up as fatigue, blurry vision, and slow wound healing. Most people have symptoms within a few weeks. Type 1 diabetes has no known direct cause, however environmental and genetic variables have both been linked to the disease (19). The pancreatic beta cells that produce insulin are attacked by and killed by the immune system. A blood test for sugar or glycated hemoglobin can identify diabetics (HbA1C). Autoantibody testing is crucial for accurately differentiating type 1 from type 2 diabetes. The majority of type 1 diabetes cases have no known preventive factors. Treatment with insulin is essential for survival. The insulin pump is an alternative to subcutaneous injections for those who require insulin therapy. [20] Regular exercise and healthy food are part of diabetes treatment. If Diabetes is not treated, diabetic complications may worsen. Diabetic ketoacidosis and nonketotic hyperosmolar coma are two outcomes that manifest quickly. Some of the long-term complications include cardiovascular disease, stroke, renal failure, foot ulcers, and eyesight loss. Consuming excessive amounts of insulin can result in dangerously low blood sugar

levels since it reduces blood sugar. [21-13] Between 5 and 10 percent of people are thought to have type 1 diabetes overall. It is unclear exactly how many people are impacted. However, it is predicted that every [24] more than 80,000 kids worldwide contract the illness. Up to three million Americans could be impacted. Scandinavia and Kuwait saw closer to thirty new cases per 100,000 people annually, compared to roughly one new case per 100,000 people in East Asia and Latin America. [25] The majority of the time, younger people experience the start of symptoms.

## **Type 2 diabetes**

The symptoms of type 2 diabetes, commonly known as adult-onset Diabetes, include excessive blood sugar, insulin resistance, and insufficient insulin production. Excessive urination, increased thirst, and unexplained weight loss are common symptoms. Additional signs could be an increase in hunger, excessive exhaustion, or an inability to heal wounds. Symptoms frequently worsen over time. Chronic effects of high blood sugar include heart disease, stroke, diabetes retinopathy-related blindness, kidney failure, and insufficient blood flow to the limbs that may require amputation. Despite the rarity of ketoacidosis, a hyperosmolar hyperglycemic condition can emerge quickly. Obesity or a lack of exercise are the two main risk factors for type 2 diabetes. Individuals have innate differences in sensitivity [26]. Type 2 diabetes makes up the great majority of diabetes diagnoses, with type 1 and pregnancy-related Diabetes making up the remaining 10%. Due to the destruction of their pancreatic beta cells, which create insulin, type 1 diabetes patients have a harder time maintaining adequate blood glucose levels. [27-28] Fasting plasma glucose, the oral glucose tolerance test, and glycated hemoglobin are examples of potential blood tests for diabetes diagnosis (A1C). Maintaining a healthy weight, engaging in regular exercise, and eating well can reduce or even eliminate the chance of developing type 2 diabetes (high in fruits and vegetables and low in sugar and saturated fats). The patient's food will be changed as part of the therapy, and she will also be urged to continue her exercise program. In the event that metformin is unable to lower blood sugar levels, insulin may be suggested as a substitute. A lot of people can require insulin injections. Some people who take oral medications might not require as frequent blood sugar checks as those who use insulin. Bariatric surgery typically benefits diabetic people. Since the 1960s, both the prevalence of type 2 diabetes and the obesity epidemic have skyrocketed. Approximately 392 million people have this diagnosis in 2015, up from 30 million in 1985. Although type 2 diabetes is growing increasingly prevalent in younger age groups, it typically does

not manifest itself until middle age or later. Expect to live 10 years less than the average person if you have type 2 diabetes. [30] The earliest known written account of Diabetes was written in Egyptian literature around 1500 BCE. [31] Insulin's medicinal benefits were first understood in the 1920s. [32]

### **Gestational Diabetes**

The medical name for high blood sugar levels that appear during pregnancy is gestational Diabetes. Although gestational Diabetes seldom causes symptoms, it may raise the risk of pre-eclampsia, depression, and the requirement for a C-section. Babies born to moms with poorly controlled gestational Diabetes were more likely to be large for gestational age at birth, to experience postnatal hypoglycemia, and to exhibit jaundice. Diabetes that is not managed raises the possibility of a stillbirth [33]. Particularly overweight kids are more likely to develop type 2 diabetes and obesity in the long run [34]. When either insulin resistance or decreased insulin production takes place during pregnancy, gestational diabetes results. Obesity, polycystic ovarian syndrome, pregnancy, and family history of the condition are all risk factors for developing Diabetes. Blood is drawn in order to make the diagnosis. It is advised to check pregnant women at average risk between the 24th and 28th week of pregnancy [35]. A high-risk pregnant woman may be examined as early as the first prenatal appointment, it has been suggested [36, 37]. Preventative measures, such as keeping a healthy weight and exercising frequently, may be helpful. In addition to a diabetic diet and regular exercise, controlling gestational Diabetes may necessitate the use of insulin injections. Most women's blood sugar levels can be controlled with dietary and activity changes. Four times a day, patients are recommended to check their blood sugar levels. After giving birth, breastfeeding should start as soon as is practical. In the study's sample of pregnant women, Diabetes affected 3-9% of them. The third trimester of pregnancy is when this frequently occurs [38]. It affects 13% of people over the age of 44 and just over 1% of people under the age of 20. Particular racial or ethnic groups are more at risk than others. This category includes people of Asian, American Indian, Indigenous Australian, and Pacific Islander descent. 90% of the time, gestational Diabetes disappears after delivery. Nevertheless, women are more likely than men to get type 2 diabetes [39].

### **Latent Autoimmune Diabetes in Adults (LADA)**

The signs and symptoms of type 1 and type 2 diabetes are identical in latent autoimmune Diabetes in adults (LADA), also known as slowly developing immune-mediated Diabetes (T2D). People with LADA frequently exhibit insulin resistance similar to individuals with type 2 diabetes (T2D), and they also share several risk factors for T2D. The study found that individuals with LADA have antibodies against the cells that produce insulin, and that this slows down the rate at which these cells quit producing insulin when compared to individuals with T1D. [40] Despite being genetically different from both T1D and T2D, it appears that LADA shares risk factors with both diseases. According to reports, insulin resistance and autoimmune disease in LADA patients can range from mild to severe, demonstrating genetic and phenotypic variability. LADA's shared genotype and phenotype, along with its intraclinical variation in autoimmune and insulin resistance, imply that it may be seen of as a hybrid form of type 1 and type 2 diabetes. The name LADA, coined in 1993[41], is not recognized by the International Diabetes Federation or the Expert Committee on the Diagnosis and Classification of Diabetes Mellitus, both of which include type 1 diabetes in their common definitions.

#### **1.4.Diabetes Symptoms**

- A) Frequently urinate (pee), often during the night
- B) abjectly starving
- C) Cloudy eyesight.
- D) Having tingly or numb hands and feet.
- E) Feeling extremely exhausted
- F) having very dry skin
- G) Wounds that progress steadily yet slowly
- H) A higher than usual number of illnesses

## **1.5.Causes**

### **Causes type 1 diabetes**

When the beta cells in the pancreas that make insulin are attacked and destroyed by the immune system, which acts as the body's line of defense against infection, type 1 diabetes results. Environmental variables, including infections and genetic predispositions, may hasten the onset of type 1 diabetes, according to scientists [42].

### **Causes type 2 diabetes**

The most prevalent type of Diabetes, type 2, has a number of genetic and environmental causes.

#### **Overweight, obese, and physically inactivity**

The likelihood of developing type 2 diabetes rises with inactivity, weight gain, and obesity. Insulin resistance is a common complication of type 2 diabetics' weight issues. The distribution of fat throughout the body has an impact on the outcomes as well. An increased risk of type 2 diabetes, insulin resistance, and cardiovascular disease has been associated with excess abdominal fat. Based on your current weight, use these Body Mass Index (BMI) statistics to estimate your level of risk for type 2 diabetes. [43]

#### **Insulin resistance**

The first sign of type 2 diabetes is frequently insulin resistance, a condition in which the body's muscle, liver, and fat cells do not react to insulin as they should. Your body consequently requires extra insulin to facilitate glucose uptake into cells. An increase in the need for insulin causes the pancreas to produce more of the hormone. The inability of the pancreas to produce enough insulin over time raises blood glucose levels.

#### **Genes and family history**

Similar to type 1 diabetes, type 2 diabetes may be more likely to develop if you have specific genes. The illness, which typically runs in families, affects these racial/ethnic groups more frequently than others:

- Black Americans
- Native Alaskans

- Indian Americans
- American Asians
- Hispanics/Latinos
- Hawaiian natives
- Caribbean Islanders

Genes may also increase a person's likelihood of being overweight or obese, which increases their risk of developing type 2 diabetes.

### **Causes of gestational**

Gestational Diabetes is thought to have hormonal changes related to pregnancy as its primary causes, in addition to hereditary and environmental factors.

#### Insulin resistance

Due to placental hormones, insulin resistance is prevalent in late pregnancy. Sadly, some pregnant women do not produce enough insulin to properly address their insulin resistance. When the pancreas does not make enough insulin, gestational Diabetes develops. Similar to type 2 diabetes, pregnancy-related Diabetes is linked to weight gain. Insulin resistance may already exist in obese or extremely overweight females. It's also possible that overeating while pregnant is a contributing factor. [44-46]

## 1.6.Diagnosis

Diabetic diagnosis may include more than one test. Testing both methods is usually necessary to confirm a diabetes diagnosis, which might add a second day to the process. Tests should be performed in a clinical setting, such as a hospital or private laboratory. If your doctor discovers that your blood glucose (blood sugar) level is very high, or if you also exhibit the typical symptoms of high blood glucose, a single positive test may be sufficient to diagnose Diabetes.

### A1C

The A1C result is a summary of your blood glucose levels over the previous 1-2 months. The approach has the added advantage of not requiring you to go without eating or drinking before the test. Diagnosis of Diabetes is made with an A1C level of 6.5% or above.

### A1C

Normal	less than 5.7%
Prediabetes	5.7% to 6.4%
Diabetes	6.5% or higher

### Fasting Plasma Glucose (FPG)

Patients who are fasting have their blood glucose levels checked. Fasting is defined as abstaining from all food and drink (other than water) for at least 8 hours before to a medical checkup. Commonly, this inspection is done first thing in the morning before eating anything. A diagnosis of Diabetes mellitus is made if a person has a fasting blood sugar level of 126 mg/dl or above.

### Fasting Plasma Glucose (FPG)

Normal	less than 100 mg/dl
Prediabetes	100 mg/dl to 125 mg/dl
Diabetes	126 mg/dl or higher

### Oral Glucose Tolerance Test (OGTT)

The OGTT checks your blood sugar levels before and after you drink a particular sweet drink. This test might tell doctors a lot about how efficiently or badly your body processes sugar. After two hours of fasting, a blood glucose level of 200 mg/dl or above is considered diagnostic of Diabetes.

#### Oral Glucose Tolerance Test (OGTT)

Normal            less than 140 mg/dl

Prediabetes      140 to 199 mg/dl

Diabetes          200 mg/dl or higher

#### **Random (also called Casual) Plasma Glucose Test**

A blood test may be done if there are serious signs of Diabetes. A diagnosis of Diabetes may be obtained if blood glucose levels are above 200 mg/dL. [47-49]

### **1.7. Diabetes Treatments**

Patients with Diabetes must strictly follow their medication regimens. Diabetes should never be ignored because the consequences could be catastrophic. The need for toe or foot amputation, blindness, renal failure (or other organ failure), and even death are possible complications. If you have Diabetes, taking your medication as prescribed can significantly lower your risk of developing a diabetic complication. A combination of medications, dietary changes, and increased physical activity is used as treatment. Among the options for managing Diabetes are pills, insulin, and other injectable medications. For people with type 1 diabetes, insulin injections are a constant necessity. Despite the fact that many people with type 2 diabetes can manage their blood sugar levels with oral medications, some may eventually require insulin. [50]

#### Endocrine Connection

Treatment options are specific for each diabetes subtype. Diabetes comes in a variety of forms, including but not limited to the following:

- A type 1 diabetes diagnosis is made when the pancreas stops producing insulin. Everyone is at risk, but children and teenagers are especially weak. People with type 1 diabetes need to take insulin to preserve their health.
- Although type 2 diabetes is the most prevalent, there are other types as well. In people with type 2 diabetes, insulin production declines and insulin resistance emerge. Adults are disproportionately affected, especially the overweight. The increased risk of developing type 2 diabetes, however, does not only apply to the elderly.
- One type of Diabetes that only manifests during pregnancy is gestational Diabetes. Fortunately, the majority of women say that their symptoms disappear after delivering delivery. Women who had gestational Diabetes had a greater lifetime risk of developing type 2 diabetes. There are numerous medication classes that can be prescribed for medicinal purposes. Although it is not required to recall all the names and technical terms, we should be aware of the fact that there are alternatives because the sheer number of them may be overwhelming. [51-52]

## 1.8.Plants

Most of the energy required by members of the eukaryotic kingdom Plantae comes from sunlight. Once upon a time, the plant kingdom was thought to include all animals not included in the animal world. However, current definitions of Plantae do not include prokaryotes and some types of algae (the archaea and bacteria). One group of plants is known as Viridiplantae, which is Latin for "green plants," and is related to Glaucophyta. It includes green algae and Embryophyta (land plants). The second category of plants includes ferns, hornworts, liverworts, trees, flowers, and mosses. The majority of plant species are multicellular creatures. The majority of the energy needed for green plants comes from photosynthesis, which is carried out by primary chloroplasts produced through an endosymbiotic relationship with cyanobacteria. They have a distinctive green color because of the presence of chlorophylls a and b in their chloroplasts. Although parasitic or mycotrophic plants can produce blooms, fruit, and seeds, these plants cannot grow normally since they lack chlorophyll and photosynthesis. Even though asexual reproduction is frequently found in plants, sexual reproduction and generational alternation are characteristics of plant life. Of the 320 000

plant species that are currently known, somewhere between 260.000 and 290.000 yield viable seed. [53] Green plants offer a sizeable amount of the world's food supply in addition to the molecular oxygen required for the majority of Earth's ecosystems to function. Since they are necessary for a balanced diet, humans have been farming grains, fruits, and vegetables for eons. Plants have been used by humans for a wide range of purposes since the beginning of time, including but not limited to food, medicine, clothing fiber, and paper. Botany is a discipline of biology that studies plants and their surroundings. [54]

## 1.9. Medicinal plants

Traditional medical practices have placed a strong emphasis on finding and using medicinal plants, also referred to as medicinal herbs, since ancient times. Plants produce a wide variety of chemicals for a variety of purposes, including protection against herbivorous animals, insects, fungi, and illnesses. The identification of numerous phytochemicals with known or anticipated biological functions has occurred recently. The benefits of employing the entire plant as a treatment remain unclear because a single plant may contain a range of phytochemicals. The phytochemical makeup and pharmacological activity, if any, of many plants with potential as medicines have not been well studied by science. [55] Clay tablets with information on hundreds of medicinal plants, including opium, were left behind by the Sumerian civilization, which peaked around 3000 B.C. A list of about 850 plant remedies can be found in the Ebers Papyrus, which was recorded in ancient Egypt around 1550 B.C. The treatise *De materia medica*, written by the Greek physician Dioscorides in the year 60 AD while he was serving in the Roman army, served as the foundation for pharmacopeias over the following 1500 years. As a result of ethnobotanical studies conducted as part of drug development efforts, hundreds of chemicals with pharmacological action have been found. Aspirin, digoxin, quinine, and opium are typical medications. There may be a vast range of molecular types in plants. Four biochemical categories—alkaloids, glycosides, polyphenols, and terpenes—are in which they are classified. Due to their low cost and wide availability, medicinal plants are frequently employed in nations that have not yet developed a manufacturing sector. In 2012, it was predicted that the yearly export value of the numerous plant species with therapeutic properties was US\$2.2 billion. [56] As of 2017, it was anticipated that the global market for plant-

## Review paper on antidiabetic plant in Bangladesh

based medicines and extracts will be worth billions of dollars. The World Health Organization (WHO) has set up a network to promote the responsible and healthy use of traditional medicine due to the lack of regulation in some nations. Over-collection to satisfy commercial demand is a specific concern for medicinal plants, in addition to general problems like climate change and habitat loss.

## Chapter Two: The Goal of My studies

## Review paper on antidiabetic plant in Bangladesh

Diabetes is a chronic condition that makes it harder for your body to turn food into usable energy. Your body absorbs the majority of the food you eat after it has been converted to glucose. Insulin is secreted by the pancreas in response to an increase in blood sugar levels. Using certain plants that have an impact on the body's glucose metabolism can help manage diabetes mellitus. Except for insulin, pramlintide, and other GLP receptor agonists, all of these medications must be taken orally and are sometimes referred to as oral hypoglycemic medications or oral antihyperglycemic medications.

My aim of this study is,

- To the bioactive compound to management of diabetes.
- To determine which plant possesses anti-diabetic qualities.
- To provide an overview of the plant's use in treating Diabetes.
- In relation to the percentage of plant compounds used to treat Diabetes in Bangladesh.
- To establish a new field of higher education.

## Chapter Three: Methodology

### **3.1. Introduction:**

A literature review leads the examination. Around 15 papers are reviewed for this study.

### **3.2. Research Design:**

This exploration was planned through google scholar, PubMed, and many other websites to find literature.

### **3.3. Method of Data Analysis:**

After an assortment of information, all information was checked for precision and internal consistency to deny missing or clashing data, and those were discarded. Information investigation was done through Microsoft's dominant refreshed rendition. All collected information is from 1999 to 2022.

### **3.4. Ethical Considerations**

Before beginning the information assortment, educated verbal permission was taken from the investigation members. The obscurity of the respondents was kept private, and study subjects were educated that they could have the option to leave the program at any.

## **Chapter Four:**

# **Result and Discussion**

**4.1. The proportion of antidiabetic plant components used to treat Diabetes in Bangladesh.**

Traditional methods of treating hyperglycemia are frequently simpler, less expensive, and produced from readily available herbs that have hypoglycemic characteristics locally. One of the few herbal remedies with antidiabetic effects that generated a lot of research interest. They are *Mangifera indica L.*, *Centella Asiatica L.*, *Terminalia chebula L.*, *Ficus racemose L.*, *Ficus hispida L.f.*, and *Momordica charantia L.* *Coccinia cordifolia L.* Cogn, *Aegle marmelos L.* *Corrêa*, *Coccinia grandis L.* Voigt F. Hook, and Thoms are the three corticolous *Tinospora* species. *Tamarindus indica L.*, *Bombax ceiba L.*, *Trigonella foenum-graecum L.*, *Kalanchoe pinnata (Lamk.) Pers.*, *Cajanus cajan L. Millsp.*, and *Clerodendrum viscosum Vent.* The entire plant is studied for potential antidiabetic properties, including the leaf, fruit, flower, root, bark, rhizome, bulb, latex, and seed. The plant's leaf, used 32% of the time, is followed in terms of frequency of use by the fruit (14%), the entire plant (12%), the root (11%), the seed (11%), the bark (9%), the stem (6%), the flower (3%), and the rhizome (1%). [57][58].

Parts of plants used in the treatment of Diabetes	Botanicals used to cure Diabetes, in part
Leaf	32%
Fruit	14%
The whole plant	12%
The root	11%
The seed	11%
The bark	9%
The stem	6%
The flower	3%
The rhizome	1%

Table 01: The proportion of antidiabetic plant components used to treat Diabetes in Bangladesh.

#### 4.2. Long-standing usage as an effective diabetes treatment

Several plant parts, including leaves, barks, seeds, fruits, stems, flowers, and in some cases, entire plants, are used to treat Diabetes, according to a thorough review of the literature. Most plants are used with water and consumed first thing in the morning. These formulas are provided in Table 2 [59][60].

Plants Name	Family	The formulation used in local areas of Bangladesh
<i>A. paniculata</i>	Acanthaceae	Drugs derived from the entire plant are frequently used to treat diabetes. 5 mg of the crude paste extract from the entire plant is taken in the morning before breakfast.
<i>A. conyzoides</i>	Asteraceae	Every day, two spoonfuls of the macerated form of the entire plant are consumed.
<i>S. chirata</i>	Gentianaceae	A mixture of honey and chirata root is used to treat diabetes. It is taken every morning in doses of 1-2 g.
<i>T. arjuna</i>	Combretaceae	Consume 3-6 g of powdered or macerated Berks with milk two hours after eating.
<i>A.indica</i>	Meliaceae	The water-based leaf extract paste should be taken twice to three times daily on an empty stomach.

Table 02: The most typical conventional preparations of the highlighted plants.

#### 4.3. Hypoglycemic effects of *A. paniculate*

According to reviewing several articles, the Aqueous *A. paniculata* extract may have inhibited glucose-induced hyperglycemia in normal rabbits but had no effect on epinephrine-induced hyperglycemia. After six weeks of consistent dosing, there is no change in the blood glucose level in the fasted state. However, various studies have demonstrated that *A. paniculata* and andrographolide can produce hypoglycemia effects by obstructing the alpha-amylase and alpha-glucosidase enzymes. In alloxan-induced diabetic rats, a potent antidiabetic efficacy was demonstrated by re-establishing the impaired estrous cycle state [61][62].

#### 4.4. Wound-healing properties of *A. conyzoides*

Normal wounds can acquire secondary infections and take a long time to heal, making it challenging for diabetic people to heal them. According to an analysis of several studies, the excision wound model is frequently employed to quantify wound-healing activities. After treating the model with plant extract and distilled water, it was found that 72% of the wounds in the group treated with the plant extracts had healed, whereas more than 90% of the wounds in the group had done so [63][64].

Group 1	Using plant extracts and distilled water, 72% of wounds were cured.
Group 2	90% of wounds were healed with only plant extracts

Table 03: Wound-healing properties of *A. conyzoides*

#### 4.5. Diabetes and other functions are impacted by *Ocimum Sanctum L.* (tulsi).

The results of the study imply that tulsi and neem leaves may be used to treat people who have Diabetes and high blood pressure by reducing their symptoms and blood pressure. There was no noticeable difference in the individuals' anthropometric measurements after tulsi and neem leaf powder were added to their diets. The aqueous leaf extract significantly lowers blood sugar levels in both healthy and alloxan-induced diabetic rats [65]. In diabetic and hypoglycemic rats, it also reduces total cholesterol, uric acid, fasting blood sugar, and hypolipidemia. [66] Only a few of the main effects include antioxidant, antibacterial, antifungal, antiviral, anti-asthmatic, antistress, anticancer, involvement of stomach ulcer, antimutagenic, and immunostimulant properties [67].

#### 4.6. Medicinal plants of Bangladesh with antidiabetic activity and Probable mechanisms of action.

There are a lot of antidiabetic medicinal plants in Bangladesh, and their bioactive components and likely modes of action are given in table: 4 below, according to research from numerous articles [68].

Botanical name (Common Name)	Bioactive constituent(s)	Probable mechanisms of action
<i>Acacia catechu</i> (L.f.) Willd.	▪ Flavonoids	Encourage insulin production Encourage regrowth of Beta-cells
<i>Adhatoda vasica</i> Nees (Basak)	▪ Alkaloids	Reduce alpha-glucosidase activity
<i>Aegle marmelos</i>	▪ Tannins	Increase insulin secretion from pancreatic $\beta$ -cell. Regulate the activity of carbohydrate metabolizing enzymes

Table 04: Bioactive constituent(s) and Probable mechanisms of action of medicinal plants

#### 4.7. Effect of Aloe vera on fasting blood glucose levels (mg/dl) in control and experimental rabbits

According to clinical studies, aloe vera gel may serve as a secure antihyperglycemic and anti hypercholesterolemic medication in people with type 2 diabetes without significantly affecting other normal blood lipid levels or liver/kidney function. Aloe vera was given to rabbits in a study to see how it affected their fasting blood glucose levels. The blood glucose-lowering effects of aloe vera and glibenclamide are both 28% and 37%, respectively [69–70].

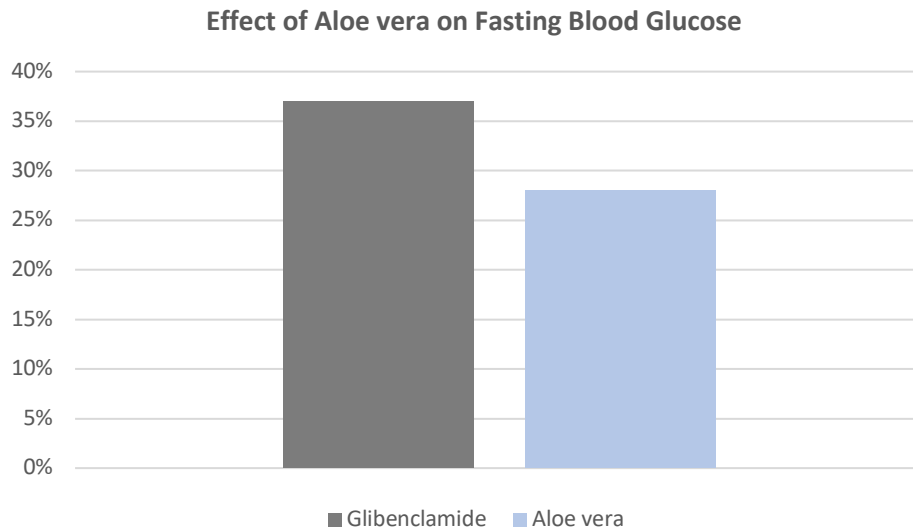

Fig 1: Effect of Aloe vera on Fasting Blood Glucose

## Chapter Five: Conclusion

A list of antidiabetic herbs used to treat diabetes mellitus has been presented by the study. It demonstrates that these herbs have hypoglycemic characteristics and can be used to treat many secondary issues associated with diabetes mellitus. Historically, plants have been a reliable source of medicine for the treatment of a wide variety of illnesses, even if many of the therapeutic compounds collected from them have not yet been fully characterized. Further investigation is required to pinpoint the precise mechanism of action of therapeutic plants with hypoglycemic and insulin-mimetic properties. Despite the widespread belief that plants are safe for humans, many of their products are really harmful. Therefore, before consuming these plants, toxicity research on them should be elucidated.
